## Dodecaphone

## Introduction

The Dodecaphone is a monophonic, semi-random sequencer based on Schoenberg's rule for serial composition, or Dodecaphony.

### Schoenberg

In the early twentieth century there was a movement away from the traditional orchestral music traditions of major versus minor keys, conventional harmony and even the notion of a piece of music having any key centre at all. The idea is that the music should be *atonal* with all twelve notes in the chromatic scale having equal weight and importance within a piece.

Schoenberg is one of the earliest, and best know, proponents of this approach and he developed a series of rules that a composer must follow to achieve this end.

The starting point of any piece of atonal music, using the Schoenberg rules, is the tone row, or series as it is sometimes called. The tone row is a sequence of twelve pitches containing every note in the chromatic scale exactly once. The row must be played in its entirety before any other notes can be employed and the piece continues by repeating the row or any combination of various transformations of the row. In each case the chosen transformation must be played right through before the next row begins.

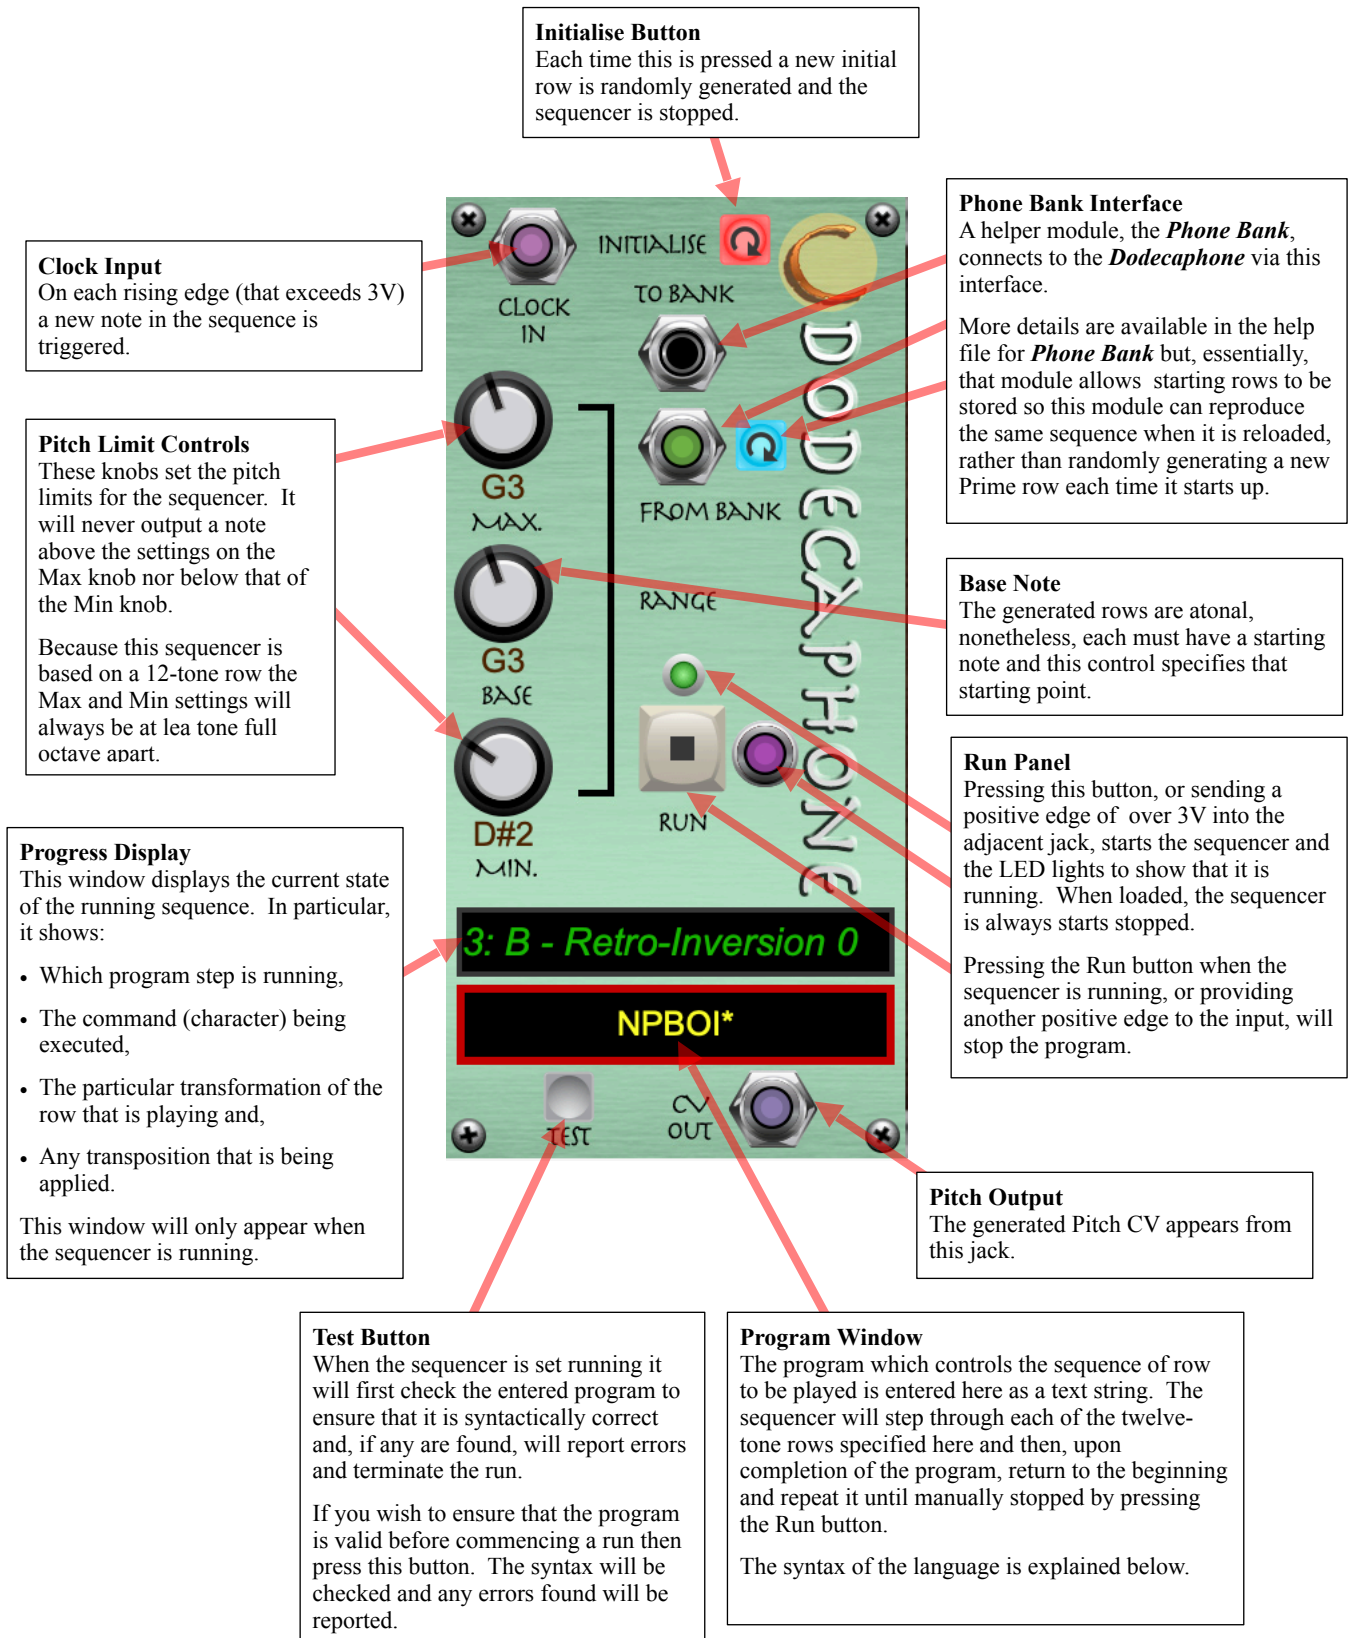

In addition to the original (**Prime**) row, the following transformations are permitted:

- **Retrograde**: the same notes as the Prime row but played in reverse.
- **Inversion**: the Prime row but with all of the intervals between note inverted.
- **Retrograde Inversion**: the Prime row inverted and reversed.

In addition, the Prime row and any of its transformations may be transposed by any number of semitones.

This sequencer randomly creates one of the 9,985,920 possible, genuinely unique Prime rows and then, based on user input through a simple text-based language, plays through the row and any of its transformation and/or transpositions as specified.

# The Interface

## Programming

Programming the Dodecaphone simply involves creating a string containing a series of *tokens* that specifying the operations to be performed in order. The possible operations are:

- Play the Prime row or one of its transformations.
- Specify a transposition for the next row to be played.
- Specify a transposition for all subsequent rows to be played.
- Randomly create a new Prime row.

## Tokens

The tokens used for each of these operations is as follows:

- Play the Prime row or one of its transformations:
  - P or O - Prime/Original row.
  - R - Retrograde row
  - I - Inverted row
  - B - Retrograde Inversions (both)
  - \* - Randomly select from one of the above
- Transpose the next row:
  - (n) - The next row will be played n semitones from what it would otherwise be played.
    - Note that n may be a positive or negative integer
- Transpose all subsequent rows:
  - [n] - All subsequent rows will be played n semitones from the original.
    - Note that n may be a positive or negative integer
    - Transpositions are not cumulative so [3]....[5] means that the next row will be transposed up 5 semitones and not 8.
- Randomly create a new Prime row:
  - N

Note that program strings are not case sensitive.

## Example

prb(3)I(11)b[-2]prb\*(1)\*n[7]i(-4)p

### Sequence of Events

When the module is loaded and the above program is executed the following occurs:

- Loading the module creates a new, random Prime row.
- P - plays that Prime row.
- R - plays the Retrograde of that row.
- B - plays the Retrograde Inversion of the row.
- (3)I - plays the Inversion of the row three semitones above its original pitch.
- (11)B - plays the Retrograde Inversion of the Prime row eleven semitones above its original pitch.
- [2] - until further notice, all rows will be played two semitones below the original, so...
- P - the Prime is played two semitones below its original pitch.
- R - the Retrograde is played two semitones below its original pitch.
- B - the Retrograde Inversion is played two semitones below its original pitch.
- \* - any of the Prime, Retrograde, Inversion or Retrograde Inversion is played at random, two semitones below original pitch.
- (1)\* - a randomly selected transformation (p, r, I, b) is selected and played one semitone below original pitch.
  - [-2] + (1)
- [7] - all subsequent rows will be played seven semitones above the original until further notice.
- I - the Inverted row is played seven semitones above the original.
- (-4)P - the Prime row is played three semitones above the original: [7] + (-4)
- The sequence has ended and so will now repeat with no transposition from the original Prime row.
